(54) Anti-corrosive paint

(67) An anti-corrosive coating composition comprises a pigment component dispersed in a film-forming binder, the pigment component comprising a salt of a polyvalent metal cation and an organic phosphonic acid containing at least two phosphonic acid groups. Generally, the molar ratio of polyvalent metal cations to

phosphonate groups in the salt is at least 0.8/n:1, where n is the valency of the metal ion. However the composition may also include a corrosion passivator capable of modifying the metal oxide film on the metal to be protected to render it more protective, the ratio of the polyphosphonate salt to the passivator being 1:1 to 50:1 by weight, and in the latter alternative it is also possible to use a lower proportion of polyvalent metal cations.

SPECIFICATION Anti-corr siv paint

This invention relates to anti-corrosive coating compositions for use as a protective coating for metal surfaces, particularly on iron and steel to avoid rusting. Anti-corrosive coatings are, for example, applied to bridges, steel structures which are exposed to weather for long periods during the erection of buildings, car, aeroplane and other vehicle bodies and components, agricultural machinery, oil installations and exposed steel work on ships. An anti-corrosive coating (a "shop primer") may be applied to freshly blasted steel plate which is to be stored before use in construction or shipbuilding.

Anti-corrosive paint generally comprises a film-forming binder and one or more pigments. The pigments which have been regarded as most efficient in preventing corrosion are red lead and the chromates, particularly zinc chromate. Unfortunately both red lead and the chromates are not considered to be health hazards. Many anti-corrosive paints sold at present contain zinc phosphate as anti-corrosive pigment, but the performance of paints containing zinc phosphate has not been as good as those containing red lead or zinc chromate. The present invention seeks to provide a paint giving better protection of iron and steel from rusting than zinc phosphate paints and without using chemicals regarded as health hazards.

Many phosphates, phosphonates and polyphosphates have been used as corrosion and scale inhibitors in aqueous systems. Among these are hydroxy-ethylidene-1,1-diphosphonic acid, also known as etidronic acid and its salts, whose use is described in British Patents Nos. 1,201,334 and 1,261,554 and U.S. Patents Nos. 3,431,217, 3,532,639 and 3,668,094, ethylene-1,1-diphosphonic acid described in British Patent No. 1,261,554 and amino compounds substituted by two or more methylene phosphonic acid groups described in British Patent No. 1,201,334 and U.S. Patent No. 3,483,133. The preparation of an underbased lead salt of etidronic acid having a molar ratio of lead to etidronate of 0.5 (ratio of lead to phosphonate groups 0.25:1) is described in U.S. Patent No. 4,020,091 and its use as a gelatinous pigment of high surface coverage power is described, although there is no mention of any anti-corrosive properties.

We have found that certain salts of organic polyphosphonates are particularly useful as anticorrosive pigments.

An anti-corrosive coating composition according to the invention comprises a pigment component 30 dispersed in a film-forming binder in which the pigment component comprises salt of a polyvalent metal 30 cation and an organic polyphosphonic acid containing at least two phosphonic acid groups. The ratio of polyvalent metal ions to phosphonate groups in the salt is generally at least 0.8/n:1, where n is the valency of the metal ion.

The corrosion inhibition achieved by anti-corrosive paints has several effects, whose relative

35 importance can differ for different uses of the paint. One effect is inhibiting the appearance of rust and the brown staining caused by rust. This is particularly important when the anti-corrosive paint is used as a primer to be covered by a paint whose main purpose is cosmetic. Another effect is inhibiting loss of metal by corrosion, which is particularly important when coating ships or industrial steel structures. A third effect is inhibiting the formation of corrosion products at the surface of the metal which would

40 reduce the adhesion of subsequent coats of paint. This is particularly important for a shop primer. Paints according to the invention can be prepared which are substantially more effective than paints containing phosphates, such as the known anti-corrosive pigment zinc phosphate, in achieving any one of these effects. The polyphosphonate salt pigment can be chosen to give a particular anti-corrosive effect, although many of the polyphosphonate salt pigments are superior to zinc phosphate in

45 substantially all respects.

One type of preferred polyphosphonate salt conforms to the general formula:-

$$M_x(R(PO_3)_mH_{(2m-xn)}),$$

where M represents a metal ion selected from zinc, manganese, magnesium, calcium, barium, aluminium, cobalt, iron, strontium, tin, zirconium, nickel, cadmium or titanium, R represents an organic radical linked to the phosphonate groups by carbon-phosphorus bonds, m is the valency of the radical R and is at least 2, n is the valency of the metal ion M and x is between 0.8 m/n and 2 m/n.

The valency m of the organic radical R is preferably 2 to 5. The polyphosphonate may be derived from a diphosphonic acid R(PO₃H₂)₂, for example a hydroxy-alkylidene-1,1-phosphonic acid of the formula:—

wher R' is a monovalent organic radical, preferably an alkyl group having 1 to 12 carbon atoms.

10

15

20

25

35

40

The polyphosphonat salt is preferably an etidronate since etidronic acid has the most phosphonat groups per unit weight of the acids of formula (I) and is available commercially. The acid formula (I) can be readily prepared by reacting a carboxylic acid R'COOH with phosphorus trichloride and hydrolysing the reaction product.

An alternative type of polyphosphonic acid is an amino compound containing at least two N-methylene-phosphonic acid groups. Such polyphosphonic acids can be prepared by the reaction of ammonia or an amine with formaldehyde and phosphorous acid. A diphosphonic acid of the formula:—

where R" is a monovalent organic radical, preferably a substituted or unsubstituted alkyl group having 1 to 12 carbon atoms such as propyl, Isopropyl, butyl, hexyl or 2-hydroxyethyl, can be prepared from a primary amine. An example of a tri-phosphonic acid R(PO₃H₂)₃ is amino-tris(methylene-phosphonic acid) N(CH₂PO(OH)₂)₃ prepared from ammonia. Examples of tetra-phosphonic acids R(PO₃H₂)₄ are alkylene diamine tetra(methylene-phosphonic acids) of the general formula:—

15] where Q is a divalent organic radical, preferably an alkylene group having 1 to 12 carbon atoms, for example ethylene diamine tetra(methylene-phosphonic acid) or hexamethylene diamine tetra(methylene phosphonic acid). An alternative form of tetraphosphonic acid is an alkylene bis(1-hydroxymethyl diphosphonic acid) of the formula:—

where Q' has the same definition as Q. Examples of pentaphosphonic acids R(PO₃H₂)₅ are dialkylene triamine penta(methylene phosphonic acids), for example diethylene triamine penta(methylene phosphonic acid) of the formula:—

Polyphosphonic acids of higher functionality, including polymeric polyphosphonic acids, can be used, for example a polyethylene imine substituted by methylene phosphonic groups and having the formula:

$$(OH)_{2}P(O)CH_{2}$$
 $\left(\begin{array}{c} N-CH_{2}-CH_{2} \\ | \\ CH_{2}PO(OH)_{2} \end{array}\right) N(CH_{2}PO(OH)_{2})_{2}$

where y is at least 3.

The optimum ratio of polyvalent metal to acid in the salt may vary for different metals; for example
we have found that zinc etidnorate is most effective in preventing corrosion when the molar ratio of zinc
to etidronate is at least 1.2:1, for example 1.4:1 to 2:1 (ratio of zinc to phosphonate groups at least
0.6:1, for example 0.7:1 to 1:1) whereas manganese etidronate is most effective at a manganese to
etidronate ratio of 1:1 to 1.5:1 (ratio of manganese to phosphorate groups of 0.5:1 to 0.75:1). Within
these ranges, salts having a lower polyvalent metal to acid ratio are generally most effective in
preventing rust staining but the salts having a higher polyvalent metal to acid ratio allow least overall
corrosion as assessed by absence of underfilm corrosion.

The complex polyphosphonate salt can be formed by reacting a basic compound of the desired metal M, for example an oxide, hydroxide or carbonate of zinc, manganese, magnesium, barium or calcium, with an organic polyphosphonic acid, for exmaple etidronic acid, in the desired molar proportions.

The salt-forming reaction is preferably carried out in aqueous medium and the sparingly soluble salt is recovered as a precipitate. Examples of basic compounds are zinc oxide, calcium hydr xide and manganese carbonat. Mixtures of basic compounds, for example zinc oxide and calcium hydr xide can

20

45

50

5

10

15.

20

35

45

be used to prepare a complex salt containing more than ne metal M. An aqueous solution of organic polyphosphonic acid can be add d to an aqueous slurry of the basic compound or vice versa. The slurry formed by the initial reaction of basic compound and acid formula (I) may be heated, for example at 50-100°C. for 10 minutes t 24 hours, to ensure completion of the salt-f rming reaction. The 5 precipitated salt is then separated and dried; it is preferably washed with water before drying to remove any highly water-soluble material, particularly unreacted polyphosphonic acid.

Alternatively a soluble salt of the metal M can be reacted with the polyphosphonic acid or a soluble salt thereof, but care must be taken to wash the product free of any cation (such as chloride)

which might promote corrosion.

The crystalline state of the complex salt varies according to the nature of the metal M, the polyphosphonic anion and the ratio of metal ion to polyphosphonate. Some metals form salts of welldefined crystalline form, whose stoichiometry and crystalline form may vary according to their method of preparation. Calcium etidronate, for example, forms two types of crystals with a calcium to etidronate ratio of 1:1, and florets of very small plate-like crystals with a calcium to etidronate ratio of 2:1. Other 15. metals tend to form precipitated salts whose crystalline form is less well-defined and whose composition varies according to the ratio of metal and etidronate used in their manufacture, with no identifiable compounds of simple stoichiometry. Zinc etidronate, for example, prepared from zinc and etidronic acid in molar ratio 1.5:1 under varying reaction conditions forms mainly agglomerated acicular crystals of overall zinc to etidronate ratio above 1.3:1 to 1.6:1.

The polyphosphonate salt may alternatively be overbased. The metal used in an overbased polyphosphonate salt is preferably a metal whose oxide is not markedly alkaline, for example zinc or manganese. For example an etidronate of a metal such as zinc may have a molar ratio of metal to acid up to 3:1. Such overbased salts may be of the general form

$M_zO_{(\underline{nz-2m})}R(PO_3)_m$

25 where M, R, m and n are defined as above and z is between 2 m/n and 3 m/n. They can be prepared by 25 reacting an excess of a basic compound of the metal M, for example zinc oxide, with a polyphosphonic acid R(PO₃)_mH_{2m}, for example etidronic acid. In some cases overbased salts may be formed using an equivalent amount of basic metal compound and polyphosphonic acid. For example zinc oxide and etidronic acid reacted at a molar ratio of 2:1 can form an amorphous precipitate with a zinc to etidronate ratio in the range 2.3:1 to 2.7:1 together with fine plate-like crystals of zinc to etidronate 30

ratio about 1.8:1. Both forms, or a mixture of them, are effective anti-corrosive pigments. The polyphosphonate salt can also contain cations from a strong base such as sodium, potassium, ammonium or substituted ammonium cations derived from amines, including quaternary ammonium cations, particularly when the metal M is present in less than a stoichiometric amount. These neutralise some or all of the excess acid groups in the salt so that the salt is less acidic in contact with water. Substitution of strong base cations for free acid groups generally increases the solubility of the salt. Such salts containing strong base cations may be of the general formula:-

M_xM'_yR(PO₃)_mH_(2m-xn-y)

where M, R, n, m and x are defined as above, M' is an alkali metal or an ammonium or substituted 40 ammonium ion and the value of y is such that (xn+y) is between m and 2m. Salts of this type can be prepared by adding a strong base, for example sodium hydroxide, potassium hydroxide or a quaternary ammonium hydroxide such as tetrabutyl ammonium hydroxide to the slurry formed by reaction of a basic compound of polyvalent metal M with polyphosphonic acid (R(PO₃)_mH_{2m} or by reacting an aqueous solution of a partial alkali metal salt of a polyphosphonic acid of the general formula:-

$$M'_{\gamma}R(PO_3)_mH_{(2m-\gamma)}$$

4.13.47 数1.13.15 (A.A.)

with the desired amount of the basic compound of metal M.

The invention includes coating compositions whose pigment component comprises salts containing both polyphosphonate anions and other anions, for example phosphate anions, formed for example by coprecipitation.

The invention also includes coating compositions whose pigment component comprises particles 50 of a substantially water-insoluble compound of a polyvalent metal reacted with an organic polyphosphonate acid so that the particles have a surface layer of metal polyphosphonate although the core of the particles may be unchanged water-insoluble metal compound. Pigments of this type may, for example, be formed by reacting an organic polyphosphonic acid with an excess of a metal oxide. The product may consist at least partly of coated oxide particles rather than a true overbased 55 polyphosphonate salt. The metal oxide can, for example, be zinc oxide, tin oxide, iron oxide or a form of alumina silica or zirconia having a proportion of hydroxyl groups at the surface of each particle. The

10

30

35

40

45

50

55

60

65

particles of the water-ins luble metal compound used to make pigments of this type should preferably be less than 100 microns diam ter, most preferably 1—20 microns.

The aqueous solubility of the polyph sphonate salt used as pigment is preferably less than 2 grams per litre, for exampl 0.01—2 grams per litre. The preferred solubility for the salt may vary according to the intended use of the coating composition. Salts used in paints which continuously or frequently come into contact with water, for example metal primers for marine use, preferably have a solubility less than 0.6 grams per litre, for example 0.02—0.1 grams per litre. The solubility of the salt is less critical when it is used in paints which contact water less frequently, for example paints for use on cars, aircraft or land based steel structures.

The film-forming binder for the anti-corrosive coating is preferably an organic polymer and can in general be any of those used in the paint industry, for example an alkyd resin, an epoxy resin, an oleoresin, a chlorinated rubber, a vinyl resin, for example polyvinyl butyral, a polyurethane, a polyester, an organic or inorganic silicate, a polyamide or an acrylic polymer. Two or more compatible film-forming organic polymers can be used in paint. An extender resin such as a hydrocarbon resin or a coal tar derivative can be present. We have found that the polyphosphonate salt of the invention gives particularly improved corrosion protection compared to known anti-corrosive pigments such as zinc phosphate when used in alkyd resins, which are the most widely used binders for protective coatings, and also gives a marked improvement when used in epoxy resins.

The polyphosphonate salt is generally used as 2 to 100 per cent by weight of the total pigment in 20 the paint, preferably as 5 to 50 per cent by weight of the total pigment.

The polyphosphonate salt can be used in conjunction with other anti-corrosive pigments. We have found that particularly good corrosion protection can be achieved by paints containing as pigments the polyphosphonate salt and a corrosion passivator. By a passivator we mean a corrosion inhibitor which acts either alone or in conjunction with another chemical species to modify the metal oxide film on the metal to be protected and render it more protective. The passivator can function without oxygen and is preferably capable of acting as an oxidising agent of the metal to be protected.

The invention thus includes an anti-corrosive coating composition comprising a pigment component dispersed in a film-forming binder, in which the pigment component comprises a salt of a polyvalent metal cation and an organic polyphosphonic acid containing at least two phosphonic acid groups and an inorganic corrosion passivator capable of modifying the metal oxide film on the metal to be protected to render it more protective, the ratio of the polyphosphonate salt to the passivator being 1:1 to 50:1 by weight. Such anti-corrosive paints containing a polyphosphonate salt and a passivator can give a superior anti-corrosive effect to paints containing a known anti-corrosive phosphate pigment such as zinc phosphate both in terms of prevention of rust staining and in terms of prevention of loss of metal by corrosion.

Examples of passivators are molybdates, vanadates, tungstates, chromates, stannates, manganates, titanates, phosphomolybdates and phosphovanadates. The passivator is preferably a salt of a divalent metal, for example zinc, calcium, manganese, magnesium, barium or strontium or a salt containing cations from a strong base such as sodium, potassium, ammonium or substituted ammonium cations as well as cations from a divalent metal. The passivator can, for example be zinc molybdate, sodium zinc molybdate, calcium molybdate, zinc vanadate, sodium zinc vanadate or zinc tungstate. Zinc chromate or potassium zinc chromate can be used, although it may be desired to have a chromate-free coating composition to avoid any possible health hazard. Molybdates and vanadates, particularly meta-vanadates, are preferred, particularly zinc molybdate, sodium zinc molybdate or zinc meta-vanadate. The passivator preferably contains zinc ions if the polyphosphonate salt does not. The passivator may be in the form of composite particles in which a molybdate or other passivator is precipitated on the surface of particles of a carrier pigment, for example sodium zinc molybdate may be in the form of a coating on a carrier pigment such as zinc oxide, titanium dioxide or talc as described in British Patent No. 1,560,826. The passivator preferably has a solubility of less than 2 grams per litre, for example 0.02 to 1 gram per litre.

The polyphosphonate salt and the passivator have synergistic effect and give better corrosion inhibition when used in a paint together than either pigment used separately. This synergistic effect is particularly marked for polyphosphonate salts having a low ratio of polyvalent metal ions to phosphonate groups, so that the ratio of metal ions to phosphonate groups in a polyphosphonate salt to be used in conjunction with a passivator can be lower than when the polyphosphonate salt is used without a passivator. In general the ratio of polyvalent metal ions to phosphonate groups in the salt is at least 0.5/n, where n is the valency of the metal ion, when the salt is used with a passivator; ratios of 0.8/n to 2/n are preferred.

Among the preferred phosphonate salts for use in conjuction with a passivator are calcium, zinc, 60 manganese, barium, magnesium or strontium salts containing 0.4—0.6 divalent metal ions per phosphonate group, for exmaple calcium etidronate having a molar ratio of calcium to etidronate groups of about 1:1. We have identified two crystalline calcium etidronates of this type. When calcium hydroxide and etidronic acid are reacted in water at a molar ratio of 0.6:1—1.2:1 and at a tomperature above 70°C, a precipitate of plate-like crystals of particle size below 50 microns is formed. When 65 calcium hydroxide and tidronic acid are reacted at the same ratio in water at below 70°C, a precipitate

15

20

40

f acicular crystals is formed. Both these crystal forms have been analysed as containing a molar ratio of calcium to etidronate between 0.9:1 and 1:1. The acicular crystals can be c inverted to the plate-like crystals by heating in water at above 70°C., for example for 30 minutes. Although both these calcium etidronates are particularly effective corrosion inhibitors when used in conjunction with a passivator, the plate-like crystals are preferred because of their lower solubility in water (generally below 0.5 grams per litre) and lower particle size.

The ratio of polyphosphonate salt to passivator in the pigment component of the paint is preferably 2:1 to 20:1 by weight, most preferably 4:1 to 10:1. Below this range increasing proportions of passivator such as a molybdate salt have an increasing effect in inhibiting corrosion but as the weight 10 of molybdate salt increases beyond 20 per cent based on the weight of the polyphosphonate salt, for example etidronate, there is no increase in corrosion inhibition. When the weight of molybdate increases beyond 50 per cent based on the weight of etidronate the corrosion inhibition may become less. While we cannot fully explain this surprising synergistic effect we believe that the passivator catalyses the formation of a corrosion-inhibiting layer at the metal surface.

The polyphosphonate salt can also be used in conjunction with other known anti-corrosive pigments such as a phosphate, for example zinc phosphate, silicate, borate, diethyldithiocarbamate or lignosulphonate or zinc dust or with an organic anti-corrosive additive such as a tannin, oxazole, imidazole, triazole, lignin, phosphate ester or borate ester. Minor amounts of a basic pigment such as calcium carbonate or zinc oxide can be used, particularly if the polyphosphonate salt gives a pH less 20 than 5 on contact with water. The calcium etidronates having a molar ratio of calcium to etidronate of about 1:1 generally give a pH of 4.5 to 5.1 on contact with water. Calcium etidronate with a molar ratio of calcium etidronate of about 2:1 gives an alkaline pH. Zinc etidronates having a molar ratio of zinc to etidronate of below about 1.4:1 generally give a pH of 3.5 or below. Zinc etidronates having a molar ratio of zinc to etidronate of above 1.6:1 generally give a pH of 6 to 7.

The coating composition of the invention can contain substantially inert pigments as well as the 25 25 polyphosphonate salt, for example titanium dioxide, talc or barytes and optionally small amounts of coloured pigments such as phthalocyanines. The pigment volume concentration of the paint is preferably 20-50 per cent depending upon the film-forming polymer used.

The coating compositions of the invention are most commonly used to prevent rusting of iron and 30 steel but can also be used in anti-corrosive paints for metal surfaces other than iron, such as galvanised 30 steel or aluminium, and can be used in pre-stressed concrete either to coat the stressing bars to prevent corrosion or as an exterior coating for the concrete to prevent rust staining.

The anti-corrosive coating is most usually applied to a metal surface by spray, roller or brush using as vehicle an organic solvent in which the film-forming binder is dissolved or dispersed. The coating may 35 'harden by evaporation of solvent, by air drying and/or by a cross-linking mechanism depending on the 35 nature of the binder. The coating can alternatively be applied from an aqueous dispersion, in which case it can be applied by spray, roller or brush or by electro-deposition using a film-forming binder which is an anionic or cationic resin. Alternatively the coating composition can be applied as a powder coating, for example by electrostatic spray, and fused and cured on the metal surface. 40 The invention is illustrated by the following Examples:—

EXAMPLES 1 TO 9

Preparation of Polyphosphonate Salts

EXAMPLE 1

184.8 grams (2.28 moles) zinc oxide was slurried at 20 per cent by weight in water and heated to 45 70°C. An aqueous solution containing 316 grams (1.52 moles) etidronic acid was diluted to 20 per 45 cent by weight and heated to 70°C. The zinc oxide slurry was pumped into the etidronic acid solution over 45 minutes with continuous stirring of both the slurry and the solution. A precipitate formed after the addition of about 20 per cent of the zinc oxide. The slurry formed was stirred for 4 hours at 60-70°C. to allow the salt-forming reaction to take place. The slurry was then cooled and filtered on a 50 Buchner funnel. The solid obtained was washed 4 times with distilled water using 2 litres of water each 50 time to wash the salt free of etidronic acid. The wet filter cake was broken up and oven dried at 110°C. to obtain about 500 grams of zinc etidronate as a white solid with needle-like crystals. The solubility of the zinc etidronate was measured by slurrying it in distilled water centrifuging and measuring the dissolved metal ion content. The metal ion content was 0.165 grams per litre indicating a pigment 55 solubility of 0.5 grams per litre. 55

EXAMPLE 2

Manganous carbonate (87.0 grams, 0.75 moles) was reacted with etidronic acid (154.0 grams, 0.75 moles) using the same procedure as in Example 1 to prepare manganese etidronate as a pink solid.

EXAMPLE 3

60

Calcium hydroxide (0.84 moles) was reacted with tidronic acid (1 mole) using the procedure of 60 Example 1 to prepare calcium etidronate in the form f plate-like crystals.

EXAMPLE 4

80.7 grams (2.00 moles) magnesium oxide was reacted with 207.8 grams (1.01 m les) etidronic acid using the procedure of Example 1 to prepare magnesium etidronate as a white solid.

EXAMPLE 5

The preparation of Example 1 was repeated using 246.4 grams zinc oxide (3.04 moles) to prepare a zinc etidronate having theoretical zinc to etidronate molar ratio of 2:1.

EXAMPLE 6

The preparation of Example 1 was repeated using 369.6 grams zinc oxide (4.56 moles) to prepare a zinc etidronate having a theoretical zinc to etidronate molar ratio of 3:1.

10 The solubilities of the pigments of Examples 2 to 6 were as follows:-

10

		Solubility in grams metal ion per litre	Solubility of pìgment in grams per litre	
15	Manganese etidronate of Example 2			15
	Calcium etidronate of Example 3	0.037	0.261	
20 .	Magnesium etidronate of Example 4	0.069	0.355	20
	Zinc etidronate of Example 5	0.045	0.114	
	Zinc etidronate of Example 6	0.034	0.078	•

25 EXAMPLE 7

25

Manganous carbonate was added portionwise to a vigorously stirred solution of etidronic acid (78.0 grams, 0.38 mole) in 42 mls of distilled water. During the addition carbon dioxide was evolved and a purple solution was produced. After the addition of 39.6 grams of carbonate a tan coloured precipitate remained. Distilled water (500 ml) was added, followed by a further 47.4 grams of 30 manganous carbonate to give a total of 0.75 mole. The mixture was stirred for 1 hour and then allowed to stand overnight. The resulting slurry was filtered, washed with distilled water and dried to give 115.3 grams of a pink solid, manganese etidronate.

30

Barium carbonate was added portionwise to stirred solution of etidronate acid (136.3 grams, 0.66 35 mole) in 1,584 mls of distilled water. A precipitate remained after the addition of 64.9 grams of the barium carbonate. A further 195.9 grams of barium carbonate was added, giving a total of 1.32 mole, and the stirred mixture was diluted with distilled water (1,500 ml).

35

The mixture was heated to 50-55°C. for 1 hour, cooled, filtered and washed with distilled water. After drying at 110°C. a white solid weighing 313.7 grams was obtained.

The white solid was stirred in distilled water (1,000 ml) and 34.2 ml of concentrated hydrochloric acid was added. The mixture was stirred for $2\frac{1}{2}$ hours, filtered, washed with distilled water and dried at 100°C. A white solid weighing 266.1 grams was obtained, barlum etidronate.

EXAMPLE 9

A 20 per cent aqueous solution of 316 grams etidronic acid was prepared as described in Example 45 1 and sodium hydroxide was added to it at a molar ratio of 1 mole sodium hydroxide to 2 moles etidronic acid to partially neutralise the acid. A 20 per cent slurry of 184.8 grams zinc oxide in water was then reacted with the partially neutralised etidronic acid solution using the procedure of Example 1 to prepare a zinc etidronate modified by sodium ions.

45

EXAMPLES 1 TO 9

50 Paint Testing

50

The etidronates prepared as described in Examples 1 to 9 above were each used as the anticorrosive pigment in an anti-corrosive paint. The etidronate was ball milled with the following ingredients until the particle size of the etidronate was 30-40 microns:-

10

15

20

25

40

		Per Cent by Weight	
-	Alkyd resin	20.0	
5	Etidronate as prepared in one of the Examples 1 to 9	16.3	
	Talc	13.5	
	Titanium dioxide	9.6	
•	Driers and additives	2.4	
	Solvent xylene	38.2	

Each anti-corrosive paint was sprayed onto steel panels at a dry film thickness of 100—200 microns. When the paint film was dry two scribes were scratched through the paint film to reveal the underlying steel in the form of a cross. The panels were then subjected to 500 hours salt spray test as specified in British Standard BS 3900. In a comparative experiment paints were prepared having the formulation given above but using zinc phosphate (to British Standard BS 5193) in place of the etidronate.

After 500 hours in the salt spray test the panels were assessed with regard to blistering, rust spotting, corrosion in and around the scribe including under-film creep from the scribe and rust staining from the scribe. The paints of Examples 1 to 9 showed superior anti-corrosive performance compared to the paint containing zinc phosphate, particularly with regard to corrosion in and around the scribe and rust staining the scribe. The panels coated with the paint of Examples 1, 2, 3, 5 and 9 showed less corrosion in all respect than the panels coated with the zinc phosphate paint. The panels coated with the zinc phosphate paint and were substantially equal to them in other respects. The panels coated with the paints of Examples 4, 7 and 8 showed less rust staining from the scribe than the panels coated with the zinc phosphate paint and were substantially equal to them in other respects.

EXAMPLE 10

Zinc etidronate prepared as described in Example 1 above was ball milled with the following ingredients to form an anti-corrosive paint in which the particle size of the zinc etidronate was 30 to 40 microns:—

30		Parts by weight	30
	Alkyd resin	20.0	
	Zinc etidronate	16.3	
	Sodium zinc molybdate	4.0	
35	Talc	13.5	35
·	Titanium dioxide	9.6	
	Dryers and additives	2.4	
	Xylene solvent	38.2	

EXAMPLES 11 AND 12

40

Anti-corrosive paints were prepared as described in Example 10 but using in Example 11 the manganese etidronate prepared in Example 2 and in Example 12 the calcium etidronate prepared in Example 3. In each of these examples all of the zinc etidronate was replaced by an equal weight of the manganese or calcium tidronate.

10

15

30

35

40

45

50

EXAMPLE 13

An anti-corrosive paint was prepared acc rding to Example 12 but increasing the amount of sodium zinc molybdat to 8.0 parts by weight.

EXAMPLE 14

An anti-corrosive paint was prepared according to Example 12 but decreasing the amount of sodium zinc molybdate to 2.0 parts by weight.

The anti-corrosive paints of each of Examples 10 to 14 were sprayed onto mild steel panels at a dry film thickness of 100 to 200 microns. When the paint film was dry two scribes were scratched through the paint film to reveal the underlying steel in the form of a cross. The panels were then

10 subjected to 1,200 hours salt spray test as specified in British Standard BS 3900. The panels were assessed after testing for resistance to rust staining and blistering both generally and at the scribe. The paint of Example 3 was tested similarly as a comparison which did not use a passivator.

Comparative tests were carried out in which the paint had the composition of Example 10 but with the zinc etidronate replaced by an equal weight of sodium zinc molybdate (comparative Example Y) or 15 the composition of Example 10 but with the calcium etidronate and sodium zinc molybdate replaced by zinc phosphate (comparative Example Z). The results are shown below:---

Example 10 --- very little rust staining, no blistering and no evidence of corrosion extending more than 1 mm from the scribe.

Example 11 - results as for Example 10.

20 Example 12 — substantially no rust staining (even less than Examples 10 and 11), no blistering and no 20 evidence of corrosion extending away from the scribe.

Ittle rust staining (but slightly more than Examples 10 and 11), no blistering and no evidence of corrosion extending more than 1 mm away from the scribe.

Example 14 -- results as for Example 12. 25 Example 3 — very little rust staining (no more than Example 10) but some blistering around the scribe.

25 Comparative Example Y --- rather more rust staining than Examples 10 to 14 and some corrosion extending more than 1 mm from the scribe.

Comparative Example Z - more rust staining than Example Y and some corrosion extending more than

The results show that the paints according to Examples 10 to 14 containing an etidronate and a molybdate passivator gave better resistance to corrosion of the steel panel than the paint of Example 3 containing an etidronate alone. The paint of Example 3 gave better resistance to corrosion and particularly to rust staining than the paints containing sodium zinc molybdate alone or zinc phosphate. Some of the panels painted according to Examples 10 to 14 and comparative Example Z were also 35 exposed to natural weathering in a severse marine environment at Coquet Island, a small island off the coast of Northumberland, England. After nine months the panels coated with the paints of Examples 10 to 14 showed very little rust staining and no creep of corrosion from the scribe; Examples 11, 12 and 14 in particular showed substantially no rust staining around the scribe. Comparative Example Z showed some rusting around the scribe and creep of corrosion from the scribe.

40 EXAMPLE 15

1,177 grams calcium hydroxide was slurried in 4,695 grams water and the slurry was added at 130.5 grams per minute to a stirred solution of 3,913 grams etidronic acid in 15.55 Kg water in the temperature range 65-78 °C. A mass of matted needles was precipitated after 30 minutes and addition of the slurry was interrupted while these were dispersed and re-dissolved in the solution. As 45 addition of the slurry was continued a precipitate of plate-like calcium etidronate crystals was formed. These were filtered, water washed and dried in a fluid bed dryer. Analysis of the product indicated a molar ratio of calcium to etirdronate of 0.94:1.

EXAMPLE 16

605 grams of a 60 per cent aqueous solution of etidronate acid was added over 100 minutes to a stirred slurry of 107.4 grams calcium hydroxide in 2 litres distilled water kept in the temperature range 20-35°C. A precipitate of acicular crystals was formed. These were filtered, water washed and dried in a fluid bed dryer. Analysis of the product indicated a molar ratio of calcium to etidronate of 0.94:1. Anti-corrosive paints were made by ball milling the following ingredients:--

20

40

-						
۲a	rts	bν	w	а	α	nt

		Example 15	Example 16	
	Short oil alkyd resin	20.0	20.0	
	Calcium etidronate plate-like crystals	16.3		
5	Calcium etidronate acicular crystals		16.3	5
	Sodium zinc molybdate precipitated onto zinc oxide	2.0	2.0	
	Talc	13.5	13.5	
	Titanium dioxide	9.6	9.6	
10	Driers and additives	2.4	2.4	10
	Xylene solvent	38.2	38.2	

The anti-corrosive paints of Examples 15 and 16 were sprayed onto mild steel panels at a dry film thickness of about 100 microns. When the paint film was dry two scribes were scratched through the paint film to reveal the underlying steel in the form of a cross.

The coated panels were subjected to a salt spray test carried out at 90°C, as specified in ASTM-B117.

15

After 250 hours in the hot salt spray test, the paints of Examples 15 to 16 showed virtually no corrosion or blistering at the scribe and none in the intact areas of the film. Both paints were better in all respects than the zinc phosphate comparison paint.

After 500 hours in the hot salt spray test, the paint of Example 16 showed some corrosion and 20 blistering at the scribe and had as much corrosion as the comparison paint. The paint of Example 15 still showed very little corrosion or blistering, even at the scribe and was markedly superior to the comparison paint.

EXAMPLES 15A AND 16A

Paints were prepared according to Examples 15 and 16 except that the amount of sodium zinc 25 molybdate precipitated onto zinc oxide was increased to 4.0 parts by weight. The paints were sprayed on mild steel panels at 100 microns thickness and scribed and then subjected to a weathering test at Coquet Island with a comparison panel painted with a zinc phosphate paint. After ten months the paints of Examples 15A and 16A showed very little rusting even at the scribe and were superior to the 30 comparison, which showed some creep of corrosion from the scribe.

30

25

EXAMPLE 17

682 grams of a 60 per cent aqueous solution of etidronic acid was added slowly to a stirred slurry of 400 grams zinc oxide in 1.45 Kg distilled water. A dense white amorphous precipitate was produced and settled when agitation had stopped to leave a clear liquor. The reaction was exothermic. The 35 mixture was filtered and the precipitate was washed with distilled water and dried at 110°C. 863 grams 35 of a zinc etidronate having a zinc to etidronate molar ratio of 2.4:1 was obtained.

As the filtered liquor cooled fine plate-like crystals were precipitated and these were filtered cold, washed and dried. 27.3 grams of a zinc etidronate having a zinc to etidronate molar ratio of 1.8:1 was obtained.

An anti-corrosive paint of 40 per cent by volume solids was prepared based on a short oil alkyd 40 resin haiving a pigment volume concentration (P.V.C.) of 40 per cent with the above zinc etidronate (the main precipitate of zinc to etidronate molar ratio 2.4:1) used as 40 per cent by volume of the pigment, the remaining pigment being titanium dioxide with a small amount of bentonite.

EXAMPLE 18

An anti-corrosive paint was prepared according to Example 17 but using the zinc etidronate as 80 per cent by volume of the pigment.

EXAMPLE 19

A two-pack epoxy anti-corrosive paint was prepared from "Epikote 1001" (Trade Mark) poxy resin and a pigment comprising 40 per cent by volume of the zinc etidronate of Example 17 with 50 thankum dioxid and a small amount of bentonite. The curing agent for the epoxy was a "Versamid"

50

5

10

(Trade Mark) amino-functional polyamide and the overall solids content was 51 per cent by volume and P.V.C. 40 per cent.

EXAMPLE 20

A two-pack epoxy anti-corrosive paint was prepared according to Example 19 but using the zinc 5 etidronate as 80 per cent by volume of the pigment.

The anti-corrosive paints of each of Examples 17 to 20 were sprayed onto mild steel panels at a dry film thickness of about 100 microns and scribed and subjected to a sait spray test at 90°C. as specified in ASTM B—117. Similarly coated panels were subjected to a humidity test according to British Standard 3900F2 (100 per cent relative humidity with temperatures cycled between 40°C. and 48°C. to ensure condensation).

As comparison, paints containing the zinc phosphate in place of zinc etidronate (samples 17A to 20A) were prepared and tested.

The panels were assessed after 1,000 hours testing according to ASTM D—1654 (Procedure B).

The results are shown in the following Table 1. The panel is assessed according to the percentage of the
area showing any corrosion fallure or blistering and rated accordingly. The film is then pared back with a
scalpel to assess whether there is underfilm corrosion, which is graded as

x --- heavy corrosion

O -- no corrosion

^{+ --} moderate corrosion

ABLE 1

	HUMIDITY TEST	Underfilm X=heavy corrosion +=medium corrosion O=no corrosion	+		+	+	О	0	+	0
,	HUMII	% area failed Rating Number	8	1	100	001,	0 10	0 10	0 10	0 10
	HOT SALT SPRAY TEST	Underfilm x=heavy corrosion +=medium corrosion Č=no corrosion	0	0	+	+	+	0	0	0
	9	% area failed Rating Number	30 4	4 8	37 3	46 2	100 001	93 0	100 001	100 001
		Panel Reference	Example 17	Example 18	Sample 17A	Sample 18A	Example 19	Example 20	Sample 19A	Sample 20A

The paints containing zinc etidronate showed substantially less corrosion in both the hot salt spray and humidity tests, both in terms of visible corrosion and underfilm corrosion.

EXAMPLE 21

400 grams of a 50 per cent by weight solution of amino tri(methylene phosphonic acid) was
5 diluted with distilled water to give a 20 per cent by weight solution and heated to 75—80°C. A 20 per
cent by weight slurry of 99.0 grams calcium hydroxide in distilled water was heated to 75—80°C. and
added to the phosphonic acid solution over 45 minutes with continual stirring. The molar ratio of
calcium hydroxide to amino tri(methylene phosphonic acid) was 2:1 (ratio of calcium to phosphonic
groups 0.67:1). Following complete addition of the slurry, the solution and the resultant precipitate was
10 held at temperature and stirred for a further two hours. The precipitate was isolated and dried.

10

5

EXAMPLES 22 TO 29

Calcium and zinc salts of various organic polyphosphonic acids were made by the procedure of Example 21 as set out in the following Table 2:—

TABLE 2

Example No.	Type of Polyphosphonic Acid	Weight of Polyphos- phonic acid	Weight of Ca(OH) ₂	Weightof ZnO	Molar Ratio of Ca or Zn to poly-phos- phonic acid	Ratio of Ca or Zn to phosphonic Groups
22	Amino tri (methylene phosphonic acid)	58.5g	41.7g	1	2.88:1	0.96:1
23	Amino tri (methylene phosphonic acid)	95.5g	ı	48.6g	1.88:1	0.63:1
24	Amino tri (methylene phosphonic acid)	81.0g	ł	68.0g	3.10:1	1:03:1
25	Éthylene dlamine tetra (methylene phosphonic acld)	81.8g	50.0g	, 1	4.0:1	1.00:1
26	Ethylene diamine tetra (methylene phosphonic acid)	81.8g	١	54.7g	4.0:1	1:00:1
27	Hexamethylene diamine tetra (methylene phosphonic acid)	92.3g	53.9g	I	4.0:1	1:00:1
28	Hexamethylene diamine tetra (methylene phosphonic acid)	92.3g	I	59.0g	4.0:1	1.00:1
29	Diethylenetriamine penta (methylene phosphoriic acid)	172.6g		66.5g	5.45:1	1:09:1

Each of the polyphosph nate salts prepared in Example s 21—29 can be used in place of calcium etidronate in the paint formulation of Example 3 to give a paint of anti-corrosive properties equal to those of the paint of Example 3.

EXAMPLE 30

1 mole sodium hydroxide was added to 1 mole etidronic acid in aqueous solution to provide a 20 per cent by weight solution. 1 mole of an aqueous slurry of calcium hydroxide was added over 30 minutes to produce a precipitate of a calcium sodium etidronate which was filtered, washed and dried. This polyphosphonate salt could be used in place of calcium etidronate in the paint formulations of Example 3 and 12 to give a paint of equal anti-corrosive properties in each case.

4.

10 EXAMPLE 31

A fast air drying industrial primer of a type used for example as a primer coating for agricultural implements was prepared by ball milling the following ingredients:—

10

	Pe	r Cent by Weight	
	Drying oil alkyd	50.23	
15	Calcium etidronate as prepared In Example 15	12,40	15
	Sodium zinc molybdate	1.55	
	Inert pigments and fillers (calcium carbonate, titanium dioxide, talc, and yellow iron oxide)	20.07	
20	Drier and additives	2.39	20.
	Xylene solvent	13.36	

The paint was applied to phosphated steel panels and was scribed as described in Example 1. The panels were then subjected to 240 hours salt spray test using the conditions of ASTM B—117. As a comparison a paint was used having the same ingredients apart from the calcium etidronate and sodium zinc molybdate and using zinc chromate (16 per cent by weight of the pigment) as the anti-corrosive pigment.

25

The panels coated with the paint of Example 24 showed hardly any evidence of corrosion after the salt spray test even at the scribe and were equal to or better than the paint containing zinc chromate both in respect of overall appearance and of absence of rusting at the scribe.

30 EXAMPLE 32

30

An automotive surfacer/primer designed to be applied to phosphated steel and to take an acrylic top coat was prepared from the following ingredients:—

	•	Parts by Weight	
	Sodium zinc molybdat	1.32	
	Calcium etidronate as prepared in Example 1	5 12.68	
6	Inert pigments (Barytes, China clay, titanium dioxide and Yellow Iron Oxide)	22.64	5
	Bentonite gel 10%	2.57	
	Carbon black predispersion 10%	4.93	
	Tall oil epoxy ester resin	20.94	
	Urea formaldehyde resin	1.37	
10	Benzoguanamine resin	2.13	10
	Driers and additives	1.24	
	n-butanol	0.69	
	Ethyl glycol monoethyl ether	0.69	
	Xylene	28.80	

15 The pigments, bentonite gel and black dispersion were dispersed in the epoxy ester resin. Xylene was added to the dispersion and it was passed through a sand mill to achieve Hegmann reading 7. The remaining ingredients were added with stirring.

The paint was sprayed on phosphated steel panels to give dry film thickness of 30—40 microns and was cured at 163°C. for 20 minutes. The panels were scribed and were subjected to 300 hours satt spray according to ASTM B—117, in conjunction with a comparison using zinc phosphate in place of the calcium etidronate and sodium zinc molybdate. The panels painted according to the invention showed no corrosion on the intact face area and a little corrosion around the scribe and were considerably less corroded than the comparison panels in both cases.

CLAIMS

1. An anti-corrosive coating composition comprising a pigment component dispersed in a film-forming binder, in which the pigment component comprises a salt comprising a polyvalent metal cation and an organic polyphosphonic acid containing at least two phosphonic acid groups, the molar ratio of polyvalent metal cations to phosphonate groups in the salt being at least 0.8/n:1, where n is the valency of the metal ion.

2. An anti-corrosive coating composition according to claim 1 in which the salt has the general formula

$$M_x R(PO_3)_m H_{(2m-xn)}$$

where M represents a metal ion selected from zinc, manganese, magnesium, calcium, barium, aluminium, cobalt, iron, strontium, tin, zirconium, nickel, cadmium and titanium, R represents an organic radical linked to the phosphonate groups by carbon-phosphorus bonds, m is the valency of the radical R 35 and is at least 2, n is the valency of the metal ion M and x is from 0.8 m/n to 2 m/n.

3. An anti-corrosive coating composition according to claim 1 or claim 2 in which the salt is a salt of a diphosphonic acid of the formula:—

where R' is a monovalent organic radical.

4. An anti-corrosive coating composition according to claim 3 in

4. An anti-corrosive coating composition according to claim 3 in which the salt is a salt of etidronic acid.

5	of an anti-corrosive coating composition according to any of claims 1 to 5 in which the salt is a salt of a mino composition according to any of claims 1 to 5 in which the salt is a zinc salt. 7. An anti-corrosive coating composition according to any of claims 1 to 5 in which the salt is a	5
J	manganese salt. 8. An anti-corrosive coating composition according to claim 1 in which the salt is of the general formula:—	_
	$M_xM'_vR(PO_3)_mH_{(2m-xn-v)}$	
10	where M, R, n, m and x are all as defined in claim 2, M' is an alkali metal ion or an ammonium or substituted ammonium ion, and the value of y is such that (xn + y) is from m to 2m. 9. An anti-corrosive coating composition according to claim 1 in which the salt is an overbased salt.	10
15	10. An anti-corrosive coating composition according to claim 9 in which the salt is a zinc etidronate having a molar ratio of zinc to etidronate groups of from 2:1 to 3:1. 11. An anti-corrosive coating composition according to claim 1 in which the salt is in the form of composite particles formed by precipitating the polyphosphonate salt on the surface of particles of a metal oxide.	15
20	12. An anti-corrosive coating composition comprising a pigment component dispersed in a film-forming binder, in which the pigment component comprises (a) a salt comprising a polyvalent metal cation and an organic polyphosphonic acid containing at least two phosphonic groups and (b) a corrosion passivator capable of modifying the metal oxide film on the metal to be protected to render it more protective, the ratio of the polyphosphonate salt (a) to the passivator (b) being 1:1 to 50:1 by	20
25	weight. 13. An anti-corrosive coating composition according to claim 12 in which the polyphosphonate salt is as defined in any of claims 1 to 3 or 5 to 11. 14. An anti-corrosive coating composition according to claim 12 or 13 in which the	25
30	polyphosphonate salt is a salt of etidronic acid. 15. An anti-corrosive coating composition according to any of claims 12 to 14 in which the polyphosphonate salt is a calcium salt. 16. An anti-corrosive coating composition according to claim 15 in which the molar ratio of	30 -
	calcium to phosphonate groups is 0.4:1 to 0.6:1. 17. An anti-corrosive coating composition according to claim 16 in which the polyphosphonate salt is a calcium etidronate having a molar ratio of calcium to etidronate groups of about 1:1 and being	•
35	predominantly in the form of plate-like crystals. 18. An anti-corrosive coating composition according to any of claims 12 to 17 in which the passivator is a molybdate, tungstate, vanadate, stannate, manganate, titanate, phosphomolybdate or phosphovanadate containing cations from a divalent metal.	35
40	19. An anti-corrosive coating composition according to claim 18 in which the passivator also contains alkali metal, ammonium or substituted ammonium cations. 20. An anti-corrosive coating composition according to any of claims 12 to 19 in which the passivator is a molybdate.	40
45	21. An anti-corrosive coating composition according to claim 20 in which the passivator is sodium zinc molybdate. 22. An anti-corrosive coating composition according to claim 20 in which the passivator is zinc	45
45	molybdate. 23. An anti-corrosive coating composition according to claim 20 in which the passivator is in the form of composite particles formed by precipitating a molybdate of a polyvalent metal on the surface of	
50	particles of a carrier pigment.	50
	25. An anti-corrosive coating composition according to any of claims 12 to 24 in which the ratio of the polyphosphonate salt to the passivator is 4:1 to 10:1 by weight. 26. An anti-corrosive coating composition comprising a polyphosphonate salt and substantially as	
55	hereinbefore described or exemplified. 27. A process for the protection of a metal surface from corrosion comprising applying to the metal surface an anti-corrosive coating composition according to any of claims 1 to 26.	55
